Single Source Shortest Path

- Applications
  - Supplying deliveries from a factory to various godowns
    - Minimum time/cost
  - KSIT: Moving from quadrangle to your class rooms
    - Minimum time taken

Single Source Shortest Path

- Goal: Given a weighted connected (directed) graph G, find shortest paths from source vertex s to each of the other vertices
- Dijkstra's algorithm
  - Approach similar to Prim's algorithm for MST
  - Computes numerical labels differently
  - Among vertices not in the tree,
    - Find the vertex v with the smallest sum
      $d_v + w(u,v)$, where
  - $u \in V$ whose shortest path found in previous iteration
  - d_v is the length of shortest path from s to v
  - $w(u,v)$ is the weight of edge $u \to v$
Example: Dijkstra's Algorithm
- Q: Construct an SSSP using Dijkstra's algo starting from vertex a

Example: Dijkstra's Algorithm
Notes on Dijkstra's Algorithm

- Proof of correctness:
  - Using induction
- Works with graph with +ve weights only
  - Build a counter example with -ve weight where Dijkstra's algorithm does not work
- Works for both directed and undirected graphs

Algorithm: Dijkstra's Algorithm

```
Algo Dijkstra(G,s)
```
// i/p: a weighted connected graph $G=(V,E)$, and src s

//   all edges are non-negative weights

//o/p: Length dv of a shortest path from s to v.

//   along with it predecessor vertex from v to s.

Initialize(Q) // priority queue of vertices is empty initially

for each vertex $v \in V$, do

    $d_v \leftarrow \infty$; $p_v \leftarrow Null$;

    Insert(Q,v,d_v) // initialize vertex priority in priority Q

$d_s \leftarrow 0$;

Decrease(Q,s,d_s)

$p_s \leftarrow Null$;

$V_T \leftarrow \varnothing$

Algorithm: Dijkstra's Algorithm...

```
Algo Dijkstra(G,s)…
   for i=0 to |V|-1 do
      u = DeleteMin(Q)  //time implememtation based
      V_T= V_T U{u}
      for every vertex w∈V-V_T adjacent to w, do
         if d_u+weight(u,w)< d_w, then
            d_w←d_u+weight(u,w)
            p_w←u
            Decrease(Q,w,d_w) //time implementation based
         fi
      end //for w∈V-V_T
   end //for i=0
 end //algo
```

Analysis: Dijkstra's Algorithm…

- Implementation using Adjacency matrix
  - Priority Q using unsorted array
  - Outer for loop (`i=0 to |V|-1`):$O(|V|)$ times
  - DeleteMin takes $O(|V|)$ times
    - Total time for all vertices: $O(|V|^2)$
  - Decrease(Q,w,d_w) takes $O(1)$ time
    - Total time for all vertices: $O(|E|)$
  - Time Complexity: $O(|V|^2)$

Analysis: Dijkstra's Algorithm

- Implementation using Adjacency List
  - Priority Q using Heap
  - Outer for loop ($i=0$ to $|V|-1$):$O(|V|)$ times
  - DeleteMin takes $O(lg|V|)$ times
    - Total time for all vertices: $O(|V|lg|V|)$
  - Decrease(Q,w,d_w) takes $O(lg|V|)$ time
    - Total time for all vertices: $O(|E|lg|V|)$
  - Time Complexity: $O(|E|lg|V|)$

Questions

- Q1: what adjustments if any need to be made in Dijkstra's algorithm to solve the single-source shortest-paths problem for directed weighted graphs.

- Ans:

  - Do we need any changes? Just follow the directed edges.

Questions

- Q2: Find a shortest path between two given vertices of a weighted graph or digraph. (This variation is called the single-pair shortest-path problem.)

- Ans:
  - Start from one vertex as source
 - Iterate the for loop till you find 2nd vertex.

Questions

- Q3: Find the shortest paths to a given vertex from each other vertex of a weighted graph. (This variation is called the single destination shortest-paths problem.)
- Ans: Undirected graph
  - Start from the destination vertex as source
  - Find the shortest path from this to all other vertices
  - Reverse the path
- Ans: directed graph
  - Reverse the direction of all edges.
  - Start from the destination vertex as source
  - Find the shortest path from this src to all other vertices
 - Reverse the path

Questions

- Q4: Solve the single-source shortest-path problem in a graph with non-negative numbers assigned to its vertices (and the length of a path defined as the sum of the vertex numbers on the path).

- Hint:
  - The weight of the edge is sum of non-negative numbers assigned to vertices of the corresponding edge.

Dijkstra vs Prim Algo
- Do both gave same tree? Consider the example
Dijkstra algo

cost=20, sum distance=28

Prim's algo

cost=15, sum distance=38

Summary

- Dijkstra's algorithm
  - Keeps shortest length for each vertex from source s
  - Keep predecessor with each vertex towards s
  - Different from Prim's algorithm
    - Dijkstra: Chooses vertex with min shortest length from source
    - Prim: chooses edges with minimum weight from curren spanning tree (and not from src)
